TEACHING DOC. 11-page code dump quarantined in reference/. Undefined word? Open doc 18 (Layer 0 atoms) and define it before continuing.

Plain opener

A LIVE hop is ink - proof something was checked - not a blank check to spend later. To actually spend (e.g. bind), you need a short-lived, single-use ticket married to one exact write (method + path + job + kind). If you try a different write, or the ticket is stale, or you replay it - halt.

Why this exists

Time gap problem: permission at time A, different dangerous action at time B. Marrying the ticket to one fingerprint closes that gap. Stale hop = museum.

Atoms in this doc

fingerprint: A hash of the exact write being authorized - so 'bind-only' cannot authorize 'bind-and-issue'.

ticket: Short-lived, single-use grant bound to that fingerprint. Default TTL is short (seconds).

redeem: Consume the ticket while presenting the same write. Fail closed on skew, mismatch, replay, dead parent.

Law

LIVE hop != spend grant. Ticket bound to write fingerprint. Redeem must present the same write.

What to hunt later in the code dump

- How fingerprint is computed
- TTL + single_use + stale_hop_cannot_spend
- redeem halt reasons
- children_cannot_outlive_parent (license fuse)

Retrieval drill

- Why is a LIVE hop not enough to spend?
- What is married about a married write?
- What is a museum hop?
